Patient Summary

You have chronic ankle instability that's causing pain and affecting how you walk. Your ankle has been weak since a previous injury, and you're also experiencing foot drop, which makes it hard to lift your foot properly when walking.

SOAP:

Subjective: Patient reports sharp pain in ankle joint when standing, particularly affecting the lateral ankle area. History includes previous ankle sprain and ongoing issues with foot drop.

Objective: Clinical examination reveals lateral ankle instability, reduced range of motion, and tenderness on palpation. Patient demonstrates altered gait pattern consistent with foot drop.

Assessment: Chronic lateral ankle instability with associated foot drop, likely secondary to previous ankle sprain. Evidence suggests possible peroneal nerve involvement and weakened ankle stabilizer muscles.
